

What is the type of this Vulnerability?

NULL pointer dereference Vulnerability

What are the secure coding violations that caused this Vulnerability?

A null pointer dereference occurs in the function `bond_ipsec_add_sa`. The code attempts to dereference `bond->curr_active_slave` without checking if it is null. This can lead to a null pointer dereference if `bond -> curr_active_slave` is indeed null

Explain the root cause of this Vulnerability

A flaw was found in the Linux kernel involving a null dereference in the function `bond_ipsec_add_sa()`. This vulnerability may lead to a local denial of service. The issue arises when the function attempts to access a slave device that is not present, resulting in a null pointer dereference. The affected component is the `bond_ipsec_add_sa()` function
